# A Brief Clarification

- Some of you seem to be confused as to what data is – whether electrons have memory...
- Data with respect to our course is the information stored within the memory of a system (Memory will be explained later. For the time being it is just a storage space.)
- **One bit of data means a logical 0 or 1** (for our understanding)
- If we say that the output of a logic gate is **1**, it means it is providing (not necessarily storing) a bit of data whose state is **1**.
- If you measure the voltage at its output it will be around 5V (or 3V). Likewise, if it is **0**, then the voltage will be 0V indicating that the data is **0**.
- So if a conducting line is somehow held at 5V (or 3V) we can say that it is carrying a bit **1** or its state is logic **1**. (Else if it is 0V, then bit **0** logic **0**)
- So deep down it means that if a bit **0** is being stored in the memory, then that particular point in the memory where we are storing the bit, is somehow being held at 0V. If the data stored is **1**, then the voltage at that point is somehow held at 5V (or 3V).
- Conceptually if I wish to store **01001000** (1 byte) then I would need the memory to hold the following voltages at 8 different points within as:

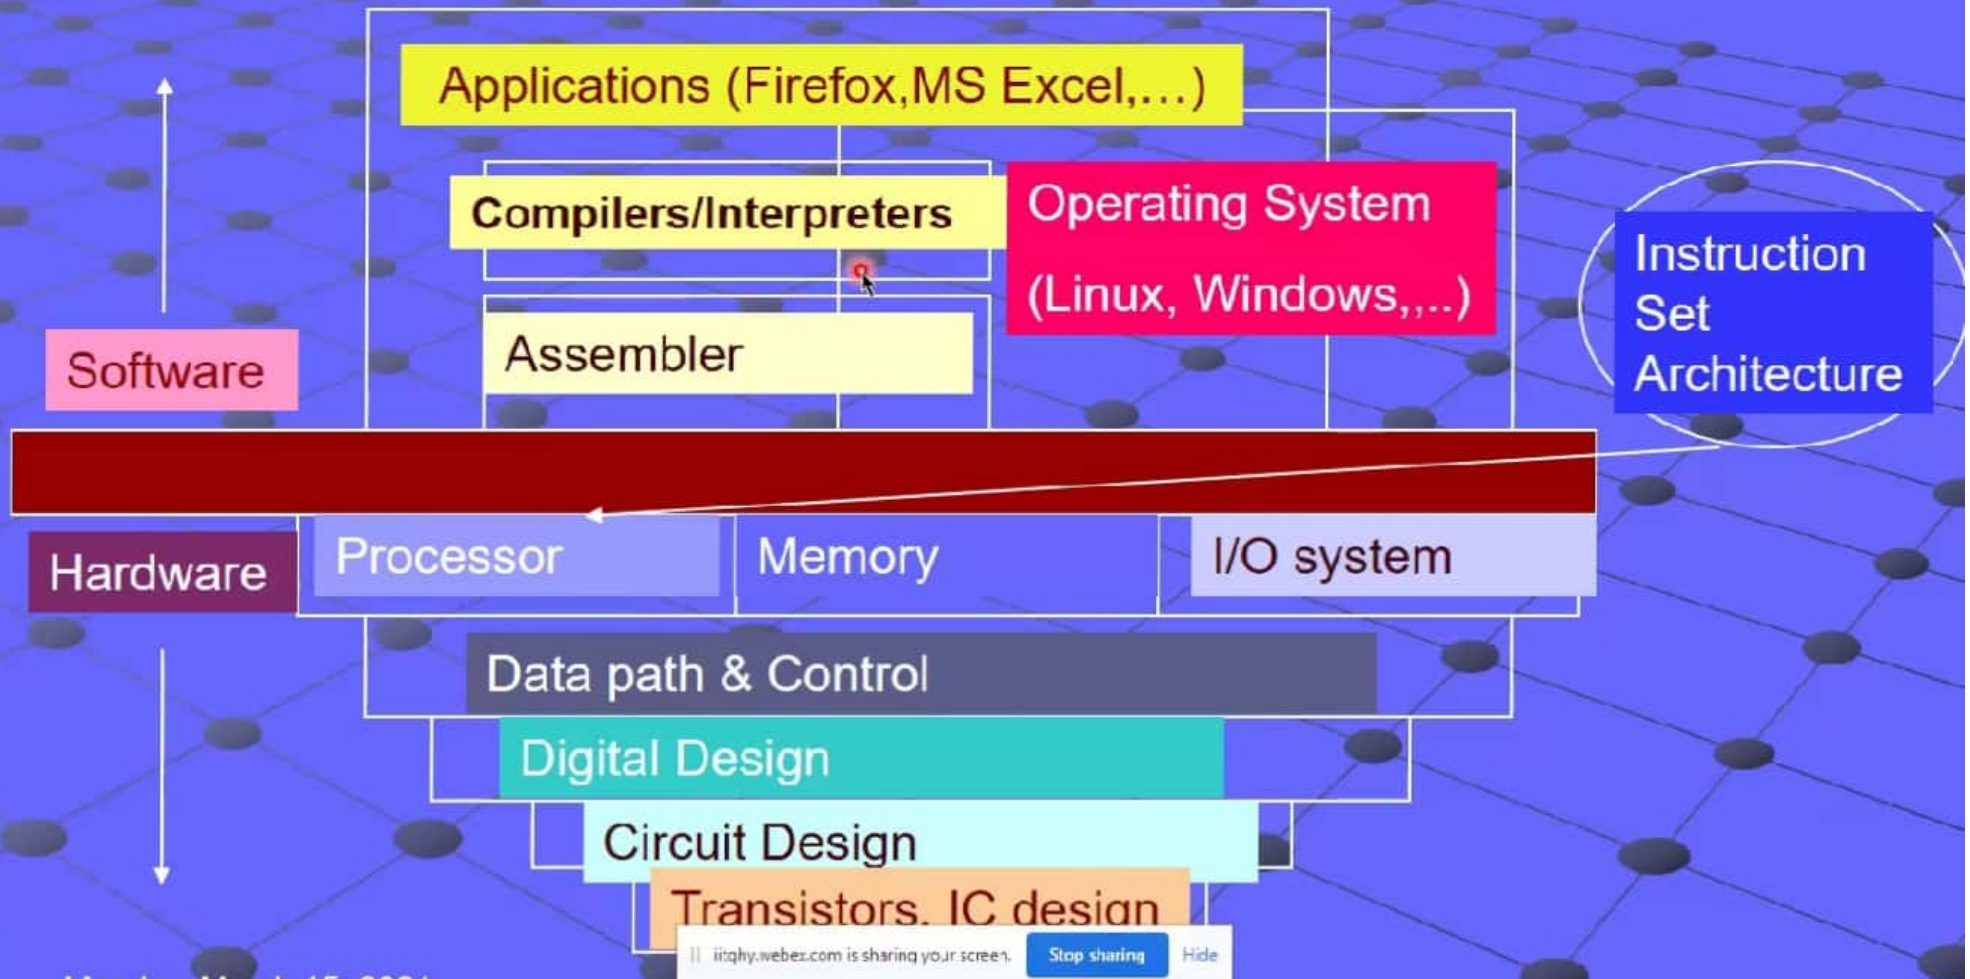

0V	5V	0V	0V	5V	0V	0V	0V	0V
----	----	----	----	----	----	----	----	----

- The above 8 blocks storing 8 bits is often referred to as an 8-bit **Register**

Coming soon: More on Memories!

# Computer Architecture = Instruction Set Architecture + Computer System Organization

Monday, March 15, 2021

# Levels Of Abstraction

- **Application Level** - All kinds of application programs written in High Level Languages
- **Compilation Level** - Each high level program is compiled into machine code
- **Operating System Level** - Set of services for managing resources of a computer
- **Instruction Set Architecture Level** - The design of this level involves specification of
  - a) Memory space
  - b) Processor registers
  - c) Instruction formats
- .....
- **Microarchitecture Level** - Implementation and Organization of hardware components including the Control Unit
- **Logic & Circuit Design Level** - Design of Components in specific technology
- **Device and Technology Level** - Manufacturing , packing etc.

# Interpreters

Ram goes to school.  
Rashid goes to school.  
Nancy goes school.  
Ram happens to be an intelligent  
guy.  
Rashid is very good at studies  
Nancy is a brilliant student.

# Compilers

Compare this with:

Reading a story sentence by  
sentence and translating it to  
another language  
(INTERPRETING)

versus

Reading the whole story,  
understanding it and then writing  
the story in the other language  
without looking at the original.  
(COMPILING)

# Interpreters

Translates the source program statement by statement into machine code.

Since only one statement is being dealt with at a time, an interpreter takes very less time to analyze the source code. But, the overall execution time of the entire program is effectively large - i.e. execution is slow.

An interpreter does not generate an intermediary code. So it does not need much of memory – in short it is efficient when it comes to use of memory.

Keeps translating the program continuously line by line till the first error is confronted. If any error is detected, it stops working and hence debugging is easier.

E.g. Python (Find more examples)

# Compilers

Scans the entire program and then translates the whole of it into machine code at once.

A compiler takes a lot of time to analyze the source code. However, the overall time taken to execute the process is much faster.

A compiler always generates an intermediary object code. Later it may need to link many aspects of the intermediary code. Hence more memory is needed.

A compiler generates the error message only after it scans the complete program and hence debugging is relatively harder.

E.g. C (Find more examples)

# Levels of Abstraction

High Level Language  
Program ( e.g., C )

Compiler

```
x = 3;  
y = 4;  
z = x + y;
```

Assembly Language  
Program

Assembler

```
MOV A, 03H  
MOV B, 04H  
ADD B  
MOV C, A
```

Machine Language  
Program

```
0000 1001 1100 0110 1010 1111 0101 1000  
1010 1111 0101 1000 0000 1001 1100 0110  
1100 0110 1010 1111 0101 1000 0000 1001  
0101 1000 0000 1001 1100 0110 1010 1111
```

Machine Interpretation

Data path Transfer  
Specification

```
IR ← Imem[PC]; PC ← PC + 1
```

NB: IR is the Instruction Register and PC is the  
Program Counter, Both these are within the  
CPU

# Memory Memorabilia

- Stores data and facilitates its retrieval at a later stage
- Conceptually, a computer memory is simply a collection of locations where information can be stored as bits
- Most often, memory **is byte-addressable**
- This means the memory is divided into **bytes** (8-bit quantities) each identified by a **unique address**
- Generally, bytes are addressed sequentially, beginning with the address 0.

Address	Byte
	7 6 5 4 3 2 1 0
0	<div><div>...</div><div></div><div></div><div></div><div></div><div></div><div></div><div></div></div>
1	80
2	45
3	67
...	
1004	22
1005	9
1006	25
...	

# Memory Memorabilia

Address Byte

7 6 5 4 3 2 1 0

0

1

- Stores data and facilitates its retrieval at a later stage
- Conceptually, a computer memory is simply a collection of locations where information can be stored as bits
- Most often, memory is **addressable**
- This means the memory is organized into **bytes** (8-bits) identified by a unique address
- Generally, bytes are accessed sequentially, beginning at address 0.

Do you give each cell in your body a name or a roll no.? You give this "whole" guy a unique Roll No. In this case a set of 8 bits (one byte) taken together is given a unique address. When you address it, all these 8 bits (1 byte) are accessed together just as when I call out a roll no. the whole of the addressed person responds!

# Size of Memory

- Generally specified as:  
No. of words x No. of bits bit/word

E.g.  $1024 \times 1 = 1\text{Kbit}$  → There are 1024 words each of 1 bit length

1Kb

$2048 \times 8 = 2\text{KByte}$  → There are 2048 words each 8 bits in length

2KB

# Memory Subsystem

Addresses are generated by the CPU to access the contents of a unique location in the memory
